## SixDesk

Version 1.0

the Simulation Environment for SixTrack

### User's Reference Manual

R. De Maria, M. Giovannozzi, E. McIntosh, A. Mereghetti, F. Schmidt, I. Zacharov Updated by: P. D. Hermes, D. Pellegrini, S. Kostoglou

#### Abstract

SIXTRACK [1, 2, 3] is a single particle tracking code widely used at CERN. One of its most important applications is the estimation of the dynamic aperture available in large storage rings like the Large Hadron Collider (LHC) or the Future Circular Collider (FCC). These studies require massive computing resources, since they consist of scans over large parameter spaces probing non-linear beam dynamics over long times. The SIXDESK [4, 5] environment is the simulation framework used to manage and control the large amount of information necessary for and produced by the studies.

This document updates the previous documentation, and describes how massive tracking campaigns can be performed with SixTrack starting from a Madx "mask" file. The SixDesk environment is an ensemble of shell scripts and configuration files, aimed at easing the everyday life of the user interested in performing large parameter scans with SixTrack.

## Chapter 1

### Introduction

SIXTRACK [1, 2, 3] is a tracking code for simulating transverse and longitudinal single particle beam dynamics. Tracking is treated in a full six-dimensional way, including synchrotron motion, in a symplectic manner. SIXTRACK is widely used at CERN for predicting dynamic aperture in large storage rings [6] like the Large Hadron Collider (LHC) [7] or its upgrade as foreseen by the High Luminosity LHC Project (HL-LHC) [8, 9].

The code was extended [10] to predict the performance of a collimation system in terms of loss pattern and cleaning inefficiency. Hence, SixTrack is routinely used nowadays also for addressing the performance of existing cleaning systems, like those of the LHC [11] or of the Relativistic Heavy Ion Collider (RHIC) at BNL [12], or new ones.

The code is in continuous development [13, 14], not only to improve the accuracy of the tracking models, but also including the dynamics introduced by novel accelerator technologies, like electron lenses or powered wires for the compensation of beam–beam long range effects or christal collimation.

The accelerator dynamic aperture is studied scanning the beam phase space in presence of non-linear forces, like the kicks introduced by long range beam—beam interactions or multipolar components of magnetic fields. Moreover, the scan could be also performed varying the machine configurations. The SIXDESK [4, 5] environment gives the users of SIXTRACK a mean to handle the large amount of files to be treated.

#### 1.1 Overview

- 1. SixTrack input generated by Madx (fort.2,fort.8, fort.16); then, run SixTrack; then, collect results (fort.10) and analyse them via SixDB;
- 2. inner loops (i.e. controlled by sixdeskenv) and outer loops (i.e. controlled by scan\_definitions);

#### 1.2 Work Flow

Show workflow of production of results, both for BOINC (including "processed" folder) and HTCondor. Retrieval of results depends on the submission platform:

• run\_results: BOINC

• run\_status: HTCondor, HTBoinc

### 1.3 Input Files

sixdeskenv

sysenv

#### fort.3.local

Geometry files: fort.2, fort.8, fort.16.

### 1.4 The BOINC Platform for Volunteering Computing

BOINC vs local batch system (e.g. HTCondor)

### 1.5 Pre-requisites

SIXDESK is native to lxplus.cern.ch. Hence, for running in such an environment, the user does not need to set up anything. On the contrary, in case of a local machine or other distributed resources,

Table 1.1: Pre-Requisites

Component	reason
kerberos	to renew/check credentials via klist and kinit
AFS (local mount)	retrieval of optics files
	submission to BOINC via spooldir
HTCondor (local installation)	submission of jobs to local batch system
python2.7	SixDB
	computation of floating point scan parameters

# Chapter 2

### **New Features**

This chapter illustrates the new features implemented in SIXDESK from the user point of view.

### 2.1 Initialisation of Workspace and Study

Original work by: A. Mereghetti

It is useful to have a standard way of setting up workspace and study from within the SIXDESK script, so that the user does not have to worry about proper template files, to be kept in sync with a given version of the scripts.

#### 2.1.1 Step-by-Step Guide

This short guide will show the user how to properly initialise a new workspace and study, step by step. In the following, the environment variable SixDeskTools is defined, e.g. as

SixDeskTools=/afs/cern.ch/project/sixtrack/SixDesk\_utilities/dev

1. set up the workspace, e.g.

```
> $SixDeskTools/utilities/bash/set_env.sh -N scratch2/wMySpace
```

This action will set up the workspace, taking care of generating the correct hierarchy between the sixjobs and the scratch\* directories. The action will create also the following tree structure:

```
> cd wMySpace/sixjobs
   > tree -h
     _ [2.0K] control_files
   | |__ [1013] fort.3.mother1_col
   | |__ [ 942] fort.3.mother1_inj
   | |__ [2.0K] fort.3.mother2_col
   | |__ [2.0K] fort.3.mother2_col_b2
   | |__ [2.0K] fort.3.mother2_inj
   | |__ [2.0K] fort.3.mother2_inj_b2
   |_{-} [2.0K] mask
   | |__ [ 39K] hl10BaseB1.mask
12
   | |__ [ 35K] hl13B1.mask
13
   | [ 0] sixdesklock
14
       [2.0K] sixdeskTaskIds
15
       [2.0K] studies
16
       |__ [ 0] sixdesklock
17
18
   4 directories, 10 files
```

- 2. go into the sixjobs dir and download templates, e.g.
- > cd wMySpace/sixjobs
- > \$SixDeskTools/utilities/bash/set\_env.sh -n -l -c

This action will generate the sixdeskenv, sysenv, fort.3.local and scan\_definitions (see Sec. 2.1) files. This action will also update the workspace, basedir and scratchdir variables in the sixdeskenv file with the correct values for the workspace just set up. Please be aware that this operation will overwrite any pre-existing file in the sixjobs dir. The templates will be downloaded from \$SixDeskTools/utilities/templates/input; in this way, templates and scripts are synchronised.

#### 2.2 fort.3.local

Original work by: A. Mereghetti

### 2.3 Enforcing the Crossing Angle

Original work by: D. Pellegrini Updated by: A. Mereghetti

### 2.4 Variable Number of Angles with Amplitude

Original work by: D. Pellegrini Updated by: S. Kostoglou, A. Mereghetti

#### 2.5 External Scans

Original work by: P. D. Hermes, D. Pellegrini Updated by: A. Mereghetti

"Internal scans" are the scans handled by SIXDESK coded in the sixdeskenv file. These are the fundamental scans used to estimate the dynamic aperture for a given machine configuration, mainly probing the beam phase space via a linear scan in particle amplitude parametric in angle. The internal scan also cover different error configurations of the magnetic fields; optionally, the user can also request to replicate the study varying the machine tune. Table 2.1 summarises essential technical characteristics of the internal scans.

Table 2.1:	Essential	technical	charact	teristics	ot	the ir	nternal	scans.
------------	-----------	-----------	---------	-----------	----	--------	---------	--------

Category	Variable	Comment
beam	amplitude	main loop in SixDesk, sub-loop in SixTrack
phase space	angle	loop in SixDesk, set point in SixTrack
machine	magnetic errors (seed)	loop in SixDesk, a MadX job each
phase space	tune	loop in SixDesk, each SixTrack job matches the tune

The internal scans make actually one study, as all the SIXTRACK input files describing the machine (i.e. fort.2, fort.8 and fort.16) are generated by a single \*.mask file. The beam phase space is scanned, and machine parameters like the multipolar errors and the tune are treated as "close" variations of the original study case.

"External" scans identify a set of additional scan parameters, not aimed at exploring further the beam phase space but machine configurations of possible interest – hence the machine "phase space" is explored. Any point in an external scan is an independent SIXDESK study, and it can be handled with the standard tools, since it has its own folder trees. But since all the studies are variations of the same machine configuration, it is logical to keep them boundled together in the same workspace, with a convenient tool which loops through them.

External scans be useful to explore the dependence of the dynamic aperture on parameters like chromaticity, octupole current, and crossing angles, for the same linear optics. Therefore, these scans are based on a 1:1 relation between MADX SIXTRACK, i.e. the knobs defined in MADX are exported as they are in SIXTRACK by means of the geometry files (i.e. fort.2, fort.8 and fort.16); this includes magnet kicks as computed by the MADX matching.

It should be noted that the present machinery set up for external scans does not modify any other parameter in the sixdeskenv and sysenv input files.

The user can define two types of external scans:

- 1. a scan over a *Cartesian grid* of an arbitrary number of variables with given steps for each variable;
- 2. a scan over a *preset list* of studies which must exist beforehand, including the sysenv, sixdeskenv and \*.mask files.

In the case of the Cartesian grid, all the studies will be named after a reference machine configuration, and the names of the scanned variables will appear explicitly in the study name, together with the values actually used for a given study.

#### 2.5.1 Input Files

The essential information is contained in the \*.mask file, used as template for the studies in the scan, and in the scan\_definitions file, describing the parameters and range of values of the scan. These two files determine the set of studies building up the external scan, whereas all the other regular input files (i.e. sixdeskenv, sysenv and fort.3.local) determine the internal scan performed in each study, and are essentially cloned, so that all points in the external scans are probed the same way.

The user defines the parameter space at their will, with no restriction due to interfaces; the user must make sure that the desired parameters can be represented by MADX and all the necessary settings are propagated to SixTrack via the geometry input files (i.e. fort.2, fort.8 and fort.16). In particular, it is responsibility of the user not only to define the variables and range of values, but also to prepare in the template \*.mask file suitable placeholders that will be recognised by SixDesk and used for differentiating the various studies. Hence, contrary to what done normally in SixDesk, the user is responsible for the proper definition of the parameter space, i.e. not only that the range of explored values is sensible, but also all the handles in the \*.mask file generate adequate input to SixTrack jobs.

More in details:

SIXDESK in all the studies involved in the scan as is, with the exception of the actual study name (i.e. LHCDescrip field), which is automatically generated as well. Hence, it is user's convenience to freeze the paramters for the internal scan before starting the external one, such that all the studies will inherit immediately the correct ones;

sysenv a regular sysenv is duplicated as is, with no further modifications by SIXDESK. As for the sixdeskenv file, it is user's convenience to set this file up before starting the external scan;

- fort.3.local the optional file fort.3.local can be used in the external scan with no specific limitations; it will be cloned as it is by SIXDESK to all bundled studies. As for the sixdeskenv and sysenv files, it is user's convenience to set this file up before starting the external scan;
- \*.mask a \*.mask file is used as template to all studies in the scan. SIXDESK will take care of cloning it to the involved studies, automatically performing the query-replace necessary to correctly set up the study. The query-replace patterns are uniquely defined by the user, and no spefic syntax is hard-coded in SIXDESK;
- scan\_definitions this is a new file to SIXDESK. It contains the full description of the scans, using a bash syntax. More than a parameter can be scanned at the same time; if it is the case, then the actual studies submitted will follow the cartesian product of all the parameter values.

Table 2.2 summarises the key facts about the input files.

File	Comments	Location
sixdeskenv	a template file for automatic query/replace	sixjobs
	must define correct settings for the internal scan	
sysenv	cloned as it is	sixjobs
*.mask	a template for automatic query/replace	mask
	must contain place holders of scanned parameters	
scan_definitions	unique	sixjobs
	it describes the scans (bash syntax)	

Table 2.2: Input files for external scans.

The user requests SIXDESK to perform a scan on the Cartesian grid or on the preset list of studies via the scan\_masks flag in the scan\_definitions file (see later); it must be set to false in case the Cartesian grid is the desired method of scanning, of to true for the preset list of studies.

#### 2.5.1.1 Scan on a Cartesian Grid

For the Cartesian grid, the variable names to be looped on in the \*.mask files are specified by the user, together with the the esplored range of values. The variables are automatically replaced by SIXDESK and the new \*.mask files created. The user defines the parameters of the Cartesian grid and the range of values that should be covered by each. In each new study, the same template \*.mask file is copied and modified according to the requirements of the user. The parameter names must match actual placeholders in the \*.mask file. The variable names to use in the \*.mask file and the values to be spanned are set in the scan\_definitions file.

The naming convention of the study (and of the \*.mask file) combines a commond name (which can identify the specific optics explored in the scan, for instance) and the name of each scanned variable with the explicit value used in each study.

The user defines in the scan\_definitions files the variable names, the placeholders used in the \*.mask file and the actual values to be scanned. Table 2.3 summarises the necessary fields, with examples.

The examples report the parameters scans for studying the dynamic aperture of the HL-LHC machine at injection; the scans are done on both beams (1 and 4, variable B and %BV as placeholder in \*.mask) with three values of chromaticity (0, 2 and 4, variable QP and %QPV as placeholder in \*.mask). Names of variables and placeholders are fully decided by the user, with no rules enforced by SIXDESK. Anyway, at set-up time, SIXDESK will check that placeholders exist in the template \*.mask file.

The template \*.mask file must be existing in the mask directory, and it must have the name specified in the scan\_prefix field in the scan\_definitions file. In the above example, the template \*.mask file would be named HLLHC\_inj.mask. The actual scan is made of 6 studies, named:

Table 2.3: Parameters controlling external scans on a Cartesian grid, to be defined by the user in the scan\_definitions file.

Parameter Name	Comment	Example
scan_variables	variable names (used in study name)	scan_variables="B QP"
scan_vals_ <vnam></vnam>	values to be explored for variable <vnam></vnam>	scan_vals_B="1 4"
		scan_vals_QP="0 2 4"
scan_placeholders	placeholders in *.mask file	scan_placeholders="%BV %QPV"
scan_prefix	common part of study name	scan_prefix="HLLHC_inj"
scan_masks	trigger to use preset list of studies	scan_masks=false

```
1 HLLHC_inj_B_1_QP_0
2 HLLHC_inj_B_1_QP_2
3 HLLHC_inj_B_1_QP_4
4 HLLHC_inj_B_4_QP_0
5 HLLHC_inj_B_4_QP_2
6 HLLHC_inj_B_4_QP_4
```

#### 2.5.1.2 Scan on a Preset List

If the user has already produced the required \*.mask files and wants to scan over a specific (sub)set of studies, he can also specify the study names explicitly. This can be useful if we want to run a command for only a subset of a larger set of studies of the Cartesian scan. To use this option, the variable listed in Tab. 2.3 are not suitable, and those described in Tab. 2.4 should be used. In the

Table 2.4: Parameters controlling external scans for a preset list of studie, to be defined by the user in the scan\_definitions file.

Parameter Name	Comment	Example
scan_masks	trigger to use preset list of studies	scan_masks=true
scan_studies	explicit list of studies in the scan	scan_studies="HLLHC_inj_B_1_QP_4
		HLLHC_inj_B_4_QP_0"

above example, the only studies which will be considered in the scan are:

```
HLLHC_inj_B_1_QP_4
HLLHC_inj_B_4_QP_0
```

As already mentioned, all the necessary input files (e.g. \*.mask, sixdeskenv, sysenv, fort.3.local, etc...) and the concerned folders (e.g. sixtrack\_input, track, work, study, etc...) must already exist.

#### 2.5.2 Implementation

The scans are handled via the scans.sh user script; it is a bash wrapper, looping the action requested by the user over the desired studies. The actual functions are coded in dot\_scan (bash) library. Hence, the user will have to deal with only the scans.sh script.

To perform a desired action on all the studies in the scan, the user just need to issue the scans.sh script using the -x action with the detailed command within double quotes. There is no need to specify the -d option of the called script, since scans.sh will automatically trigger the requeted command on each study in the scan separately. The script will take care of looping over all the studies and issue the requested command on each study. The only exceptions are the generation of the actual \*.mask\*

files, achieved via the -m action, and the set up of the directories of each study, achieved via the -s action.

When generating the \*.mask files, the script checks beforehand that all the placeholders that the user is going to use are found in the \*.mask template file. To disable this option, please use the -m option.

The use of the fort.3.local file can be triggered via the -1 option, with no need to replicate it also in the string passed through the -x action.

A very basic parallelisation of the scan is available. The user can split the final scan into smaller ones. Each of them must have its own scan\_definitions files, with a unique name. Then, the same number of instances of the scans.sh can be issued, each with the -d option, specifying the name of the scan\_definitions instance to be used.

#### 2.5.3 Step-by-Step Guide

This little guide will show the user how to set-up an the external scan and how to proceed, step by step. The reference guide is given for a scan on a Cartesian grid started from scratch, whereas some remarks will be done for the preset list of studies.

- 1. set up your workspace and download template files (see Sec. 2.1);
- 2. edit all the necessary files, e.g.
  - (a) sixdeskenv and sysenv, properly setting up the internal scans, versions of codes, etc... Please, make sure that the xing variable in sixdeskenv is not active (see Sec. 2.3);
  - (b) template \*.mask file in the mask directory, and scan\_definitions. Please make sure that:
    - scan\_prefix matches the name of the template \*.mask file;
    - the lists contained in scan\_variables and scan\_placeholders match;
    - for every variable scanned (e.g. QP), you have the corresponding list of values defined in the scan\_vals\_\* (e.g. scan\_vals\_QP);
    - all the placeholders defined in scan\_placeholders are actually in the \*.mask template file, and in the correct positions. Please keep in mind that the query/replace will be performed via a sed command.
- 3. generate all the necessary \*.mask file and the studies, e.g.
- > \$SixDeskTools/utilities/bash/scans.sh -m -s -l

The -1 option is illustrated in the example. If the fort.3.local file is not required, please ignore it. The -m action (i.e. generation of \*.mask files) and the -s action (i.e. set up of studies) can be performed separately;

- 4. run MADX and generate the geometry files for the SIXTRACK jobs, e.g.
- > \$SixDeskTools/utilities/bash/scans.sh -x "mad6t.sh -s"

Once the jobs are over, it is good practice to check them before running SixTrack, to avoid mis-submissions in case something went wrong with the MadX jobs. Checking can be performed e.g.

- > \$SixDeskTools/utilities/bash/scans.sh -x "mad6t.sh -c"
- 5. submit the actual SixTrack jobs, e.g.
- > \$SixDeskTools/utilities/bash/scans.sh -x "run\_six.sh -a -p BOINC"
- 6. download results and update job database
- > \$SixDeskTools/utilities/bash/scans.sh -x "run\_results"

## Chapter 3

# Giudelines and Common Pitfalls

#### 3.1 Choice of Platform

HTCondor is convenient when:

- 1. results should be collected quickly. This can be the case when the user has short time to collect data or the simulation set-up is being defined. In the second case, indeed, one does not want to wait too long for proceeding;
- 2. short or few jobs per study. This can be the case when re-submission of selected cases is necessary, e.g. to complete a study when few points in the scan are missing;

The BOINC platform for volunteer computing is convenient in case of large simulation campaigns, i.e. when simulations are long or they are in high number (e.g. hundreds of thousands of jobs). Not more than 5 scripts per user running at the same time, for ease of functionality of afs.
